0.1 Scaling theory

It is used whenever you have a collective behaviour. The length scale of the problem are a, L, ξ , but ξ is the only relevant length scale in the problem.

Which are the experimental data which gives us this ideas? What you can see from experiment is

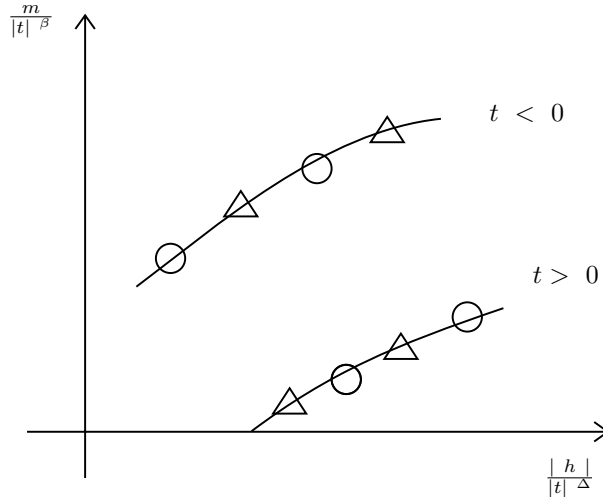

Figure 1: Description.

Widom \rightarrow static scaling theory \rightarrow homogeneous functions.

0.1.1 Single variable r

$f(r)$ is homogeneous in r , if $\forall \lambda \in \mathbb{R}$ we have $f(\lambda r) = \lambda f(r)$. More general,

$$f(\lambda r) = g(\lambda)f(r) \quad (1)$$

Example 1.

$$f(r) = Br^2 \quad (2)$$

$$f(\lambda r) = B(\lambda r)^2 = \lambda^2 f(r) \Rightarrow g(\lambda) = \lambda^2 \quad (3)$$

Sine it is valid for any λ , you can choose also a λ in that way

$$f(r) = f(\lambda r_0) = g(\lambda)f(r_0) \quad (4)$$

Theorem 0.1.1.

$$g(\lambda) = \lambda^p \quad (5)$$

where p is the degree of the homogeneity of the function.

We can make it for any variable, not only for a single one.

0.1.2 Generalized homogeneous functions

We are discussing $f(x, y)$, that is a generalized homogeneous function if $f(\lambda^a x, \lambda^b y) = \lambda f(x, y)$. In general any polynomial is a generalized homogeneous function. If we choose $\lambda^p \equiv s$, we have

$$f(s^{a/p}x, s^{b/p}y) = s f(x, y) \quad (6)$$

Consider $t \equiv \frac{T-T_c}{T_c}$, $h = \frac{H-H_c}{H_c}$

$$f(T, H) = f_{ANA}(T, H) + f_{SING}(t, h) \quad (7)$$

where f_{ANA} is an analytic term and f_{SING} diverges, has a singularity.

The singular part of the free energy

$$f_s(\lambda^{p_1}t, \lambda^{p_2}h) = \lambda f_s(t, h) \quad (8)$$

where $\forall \lambda \in \mathbb{R}$.

Another important feature, choose λ as

$$\lambda = h^{-1/p_2} \Rightarrow f_s(t, h) = h^{1/p_2} f_s(h^{-p_1/p_2}t, 1) \quad (9)$$

$$\Delta \equiv \frac{p_1}{p_2} \quad (10)$$

is called the *gap exponent*.

M is the first derivative of f with respect to H .

$$\lambda^{p_2} M_s(\lambda^{p_1}t, \lambda^{p_2}h) = \lambda M_s(t, h) \quad (11)$$

so you have the same story for the magnetization. Consider $h = 0$ and $t \rightarrow 0^-$, we have

$$M_s(t) \sim (-t)^\beta \quad (12)$$

starting from this one try to figure out what is happening at this level.

$$M_s(t, 0) = \lambda^{p_2-1} M_s(\lambda^{p_1}t, 0) \quad (13)$$

$$\lambda^{p_1}t = -1 \Rightarrow \lambda = (t)^{-1/p_1} \quad (14)$$

so

$$M_s(t, 0) = -(t)^{\frac{1-p_2}{p_1}} M_s(-1, 0) \quad (15)$$

$$\beta = \frac{1-p_2}{p_1} \quad (16)$$

For δ , we have $T = T_c$ and $h \rightarrow 0^+$, so the magnetization goes like $M_s \sim h^{1/\delta}$.

$$M_s(0, h) = \lambda^{p_2-1} M_s(0, \lambda^{p_2}h) \quad (17)$$

Now we want

$$\lambda^{p_1}h = 1 \Rightarrow \lambda = h^{-1/p_2} \quad (18)$$

$$M_s(0, h) = h^{\frac{1-p_2}{p_2}} M_s(0, +1) \quad (19)$$

$$\delta = \frac{p_2}{1-p_2} \quad (20)$$

From this you have a very simple relation

$$p_1 = \frac{1}{\beta(\delta+1)}, \quad p_2 = \frac{\delta}{\delta+1} \quad (21)$$

$$\frac{p_2}{p_1} = \Delta = \beta\delta \quad (22)$$

Our relations are

$$f_s(\lambda^{p_1}t, \lambda^{p_2}h) = \lambda f_s(t, h) \quad (23)$$

$$M_s(t, h) = \lambda^{p_2-1} M_s(\lambda^{p_1}t, \lambda^{p_2}h) \quad (24)$$

We have $\lambda = |t|^{-1/p_1}$

$$M_s(t, h) = |t|^{\frac{1-p_2}{p_1}} M_s\left(\frac{t}{|t|}, \frac{h}{|t|^\Delta}\right) \quad (25)$$

$$\frac{M_s(t, h)}{|t|^\beta} = M_s\left(\frac{t}{|t|}, \frac{h}{|t|^\Delta}\right) \quad (26)$$

By using these hypothesis you can get equalities. All the inequality that you have in thermodynamics becomes equalities. In particular, we have the Griffit relation

$$\alpha + \beta(\delta + 1) = 2 \quad (27)$$

and the Rushbrooks relation

$$\alpha + 2\beta + \gamma = 2 \quad (28)$$

0.2 Kadanoff 1966

How can we relate the coupling costant of the two hamiltonian. This is the idea of the renormalization group.

$$-\beta\mathcal{H}_\Omega = k \sum_{\langle ij \rangle} \sigma_i \sigma_j + h \sum_i \sigma_i \quad (29)$$

with

$$\sigma_i = \pm 1, \quad k \equiv \frac{J}{k_B T}, \quad h \equiv \frac{H}{k_B T} \quad (30)$$

we assume

$$r \ll \xi \quad \Rightarrow \quad a \ll la \ll \xi(t) \quad (31)$$

We can build up many procedure. This is the *Block spin transformation*, the idea is divide into cell of length la (figure 2) and we replace it with (figure 3).

$$S_I \equiv \frac{1}{|m_l|} \frac{1}{l^D} \sum_{i \in I} \sigma_i \quad (32)$$

with the sum is over all the sites with a given cell. Define the magnetization

$$m_l \equiv \frac{1}{l^D} \sum_{i \in I} \sigma_i \quad (33)$$

The frist assumption is that the Hamiltonian of the new system \mathcal{H}_l is equal in form to \mathcal{H}_Ω . It means that we can write

$$-\beta\mathcal{H}_l = k_l \sum_{\langle IJ \rangle} S_I S_J + h_l \sum_I S_I \quad (34)$$

How you measure in the new system the lengths? the correlations lengths. Before we have changed the size of the system. We have increased the ruler, so the number is smaller now. It seems stupid but it is fundamental.
